

## Session 6. Dynamic Programming

In most applications, **dynamic programming** obtains solutions by working *backward* from the end of a problem toward the beginning, thus breaking up a large unwieldy problem into a series of smaller, more tractable problems.

### \* Characteristic of DP Formulation

1. The problem can be divided into *stages* with a decision required at each stage *i*.
2. Each stage has a number of *states*  $s_i$  associated with it.
3. The *decision*  $d_i$  chosen at any stage *i* describes how the state at the current stage is transformed into the state at the next stage.
4. Given the current *state*, the optimal decision for each of the remaining *stages* must *not* depend on previously reached states or previously chosen decisions. This idea is known as the “**principle of optimality**”.
5. When a DP problem has been classified into a series of *T* *stages*, there must be a *recursion* that relates the cost (or reward) incurred at stage *i* to the cost (or reward) incurred from stages *i*+1, *i*+2, ..., *T*. In essence, the recursive relationship formalizes the working-backward procedure.

$$f_i(s_i) = \min_{\forall d_i} \{c_i(d_i, s_i) + f_{i+1}(s_{i+1})\} \text{ where } s_{i+1} = h(d_i, s_i)$$

### \* Classifications

- *Deterministic* dynamic programming
- *Probabilistic* dynamic programming

## A. Recurrence Relation

### \* Recursive Equation

- In mathematics, a **recurrence relation** is an equation that *recursively* defines a sequence; once one or more initial terms are given, each further term of the sequence is defined as a function of the preceding terms.
- A **recursive equation** can be thought of as analogous to a flight of stairs. In order to climb a **flight of stairs**, we need to be able to do the following:
  1. Get to the first step. Mathematically, this is called the *boundary* condition (or *terminal* condition in backward recursions.) For more complicated recursive equations, we sometimes need several initial conditions.
  2. Get to the next step from the previous step. Mathematically, this is the *recursive equation*.

**Ex 1] Fibonacci sequence:** The **Fibonacci numbers** are the numbers in the following integer sequence:

1, 1, 2, 3, 5, 8, 13, 21, ...

The sequence  $F_n$  of Fibonacci numbers is defined by the **recurrence relation**:

$$F_n = F_{n-1} + F_{n-2}, \text{ for } n=3, 4, \dots$$

with the **initial conditions**,  $F_1 = 1$  and  $F_2 = 1$ .

# Explicit equation? 
$$F_n = \frac{(0.5+0.5\sqrt{5})^n - (0.5-0.5\sqrt{5})^n}{\sqrt{5}}.$$

**Ex 2] Best-of-Seven Series:** Consider a **best-of-seven series** that ends when one team wins **four** games (as in the NBA, MLB, or NHL playoffs). If the probability of team **A** defeating team **B** in any game is  $p$ , find the **average number** of games in the series. (For simplicity, let us assume that each team has a **constant** probability of winning a game throughout the series and games are **independent** of each other.)

(a) **Explicit equations:** *Negative binomial* distribution

$$E[n] = \sum_{i=4}^7 i \left\{ \binom{i-1}{3} p^4 q^{i-4} + \binom{i-1}{3} p^{i-4} q^4 \right\}.$$

(b) **Recursive equations**

Let  $S(i, j)$  be the expected number of **remaining** games, given that Team A has won  $i$  games and Team B has won  $j$  games so far. Then, the **recursive equation** is

$$S(i, j) = p S(i + 1, j) + q S(i, j + 1) + 1$$

with the **terminal** (or boundary) **condition**,

$$S(i, j) = 0 \text{ if } i=4 \text{ or } j=4.$$

For example, if  $p=q=0.5$ , then  $E[n]=S(0, 0)=$

|                              |          |                           |          |          |          |          |
|------------------------------|----------|---------------------------|----------|----------|----------|----------|
| <b>Team B</b><br>( $q=0.5$ ) | <b>4</b> | 0                         | 0        | 0        | 0        | -        |
|                              | <b>3</b> | 1.875                     | 1.75     | 1.5      | 1        | 0        |
|                              | <b>2</b> | 3.5                       | 3.125    | 2.5      |          | 0        |
|                              | <b>1</b> | 4.8125                    | 4.125    |          | 1.75     | 0        |
|                              | <b>0</b> |                           | 4.8125   | 3.5      | 1.875    | 0        |
|                              |          | <b>0</b>                  | <b>1</b> | <b>2</b> | <b>3</b> | <b>4</b> |
|                              |          | <b>Team A</b> ( $p=0.5$ ) |          |          |          |          |

# Find the **recursive equation** for the **probability** that **Team A** will win the-best-of-seven series.

## B. Various Recursions

The recursive equation could be expressed as an **additive**, **multiplicative**, or **mini-max** recursion in **dynamic programming**.

### I. Additive Recursion

I. Q. Smart needs to drive from city 1 to city 5. The length  $c_{ij}$  of the arc connecting city  $i$  and city  $j$  represents the **distance** from city  $i$  to city  $j$ . Find the **shortest path**.

#### ▪ Optimality equation

Let  $f_i(s_i)$  be the **minimum distance** at stage  $i$  when the state is  $s_i$ . Then, the optimality equation is

$$f_i(s_i) = \min \{ c(s_i, d_i) + f_{i+1}(d_i) \} \text{ for all } d_i.$$

#### ▪ Optimality table:

| Stage | Decision, $d_i$ | State, $s_i$ |   |    |    |   |   |
|-------|-----------------|--------------|---|----|----|---|---|
|       |                 | 1            | 2 | 3  | 3' | 4 | 5 |
| 3     | 5               |              |   |    | 8  | 7 |   |
|       | min             |              |   |    | 8  | 7 |   |
| 2     | 3'              |              |   | 8  |    |   |   |
|       | 4               |              |   | 10 |    |   |   |
|       | min             |              |   | 8  |    |   |   |
| 1     | 2               | 14           |   |    |    |   |   |
|       | 3               | 17           |   |    |    |   |   |
|       | min             | 14           |   |    |    |   |   |

#### ▪ Optimal decision:

## II. Multiplicative Recursion

Unfortunately, some routes are heavily patrolled by police. Smart thus decided to choose a route that **maximizes** the **probability** of not being stopped by police. Observing all the feasible road segments, the **associated probabilities** were compiled as given below:

Find the route which gives the **maximum probability** of not being stopped by police.

### ▪ Optimality table:

| Stage | 1 | 2     | 3      | 4   | 5     | Max         |
|-------|---|-------|--------|-----|-------|-------------|
| 4     | - | -     | -      | -   | 0.8   | 0.8         |
| 3     | - | -     | -      | .64 | [0.7] | 0.7         |
| 2     | - | -     | -      | -   | -     | -           |
| 1     | - | 0.441 | [0.56] | -   | -     | <b>0.56</b> |

### ▪ Optimality equation

Let  $f_i$  = **probability** of driving from city  $i$  to the destination without being stopped by police.

$$f_5 = 1.0 \quad \text{<= Terminal condition!}$$

$$f_4 = 0.8 f_5 = 0.8$$

$$f_3 = \max\{ 0.8 f_4, 0.7 f_5 \} = \max\{ 0.64, 0.70 \} = 0.70$$

$$f_2 = \max\{ 0.9 f_3, 0.6 f_4 \} = \max\{ 0.63, 0.48 \} = 0.63$$

$$f_1 = \max\{ 0.7 f_2, 0.8 f_3 \} = \max\{ 0.441, 0.56 \} = 0.56$$

### ▪ Optimal decision:

### III. Min-Max Recursion

I. Q. Smart is interested in *minimizing* the **maximum altitude** above sea level that he will encounter during his drive. Now  $a_{ij}$  of the arc connecting city  $i$  and city  $j$  represents the **maximum altitude** (in thousands of feet above sea level) encountered when driving from city  $i$  to city  $j$ .

Determine how Smart should proceed from city 1 to city 5.

▪ **Optimality table:**

| Stage | 1 | 2   | 3 | 4 | 5   | Min      |
|-------|---|-----|---|---|-----|----------|
| 4     | - | -   | - | - | 7   | 7        |
| 3     | - | -   | - | 7 | [4] | 4        |
| 2     | - | -   | - | - | -   | -        |
| 1     | - | [5] | 7 | - | -   | <b>5</b> |

▪ **Optimality equation**

Let  $f_i$  = **maximum altitude** encountered when driving from city  $i$  to the destination.

$$f_5 = 0.0 \quad \leq \text{Terminal condition!}$$

$$f_4 = \max \{ 7, f_5 \} = 7$$

$$f_3 = \min \{ \max[ 6, f_4 ], \max[ 4, f_5 ] \} = \min \{ 7, 4 \} = 4$$

$$f_2 = \min \{ \max[ 5, f_3 ], \max[ 4, f_4 ] \} = \min \{ 5, 7 \} = 5$$

$$f_1 = \min \{ \max[ 2, f_2 ], \max[ 7, f_3 ] \} = \min \{ 5, 7 \} = 5$$

▪ **Optimal decision:**

### C. Deterministic DP Models

#### Ex 1] Optimal Assignment Problem

The number of **crimes** in each of a city's three **police precincts** depends on the number of **patrol cars** assigned to each precinct.

| $c_{ij}$   | Number of patrol cars assigned to a precinct |    |    |    |
|------------|--|----|----|----|
|            | 0  | 1  | 2  | 3  |
| Precinct 1 | 14   | 10 | 7  | 4  |
| Precinct 2 | 25   | 19 | 16 | 14 |
| Precinct 3 | 20   | 14 | 11 | 8  |

A total of 3 **patrol cars** are available. Determine how many patrol cars should be assigned to each precinct.

#### (a) IP formulation

- **Variables:**
- **Objective function:**
- **Constraints:**

#### (b) Network representation: Shortest path problem!

**(c) DP formulation**

- **Stage  $i$ :** Precinct  $i$ , where  $i = 1, 2$ , and  $3$ .
- **State  $s_i$  at stage  $i$ :** Total number of patrol cars available.
- **Decision  $d_i$ :** Number of cars assigned to precinct  $i$ .
- **Optimality equation:**

Let  $f_i(d_i, s_i)$  be the minimum number of crimes at stage  $i$  when the state is  $s_i$  and the action is  $d_i$ . Then, we have

$$f_i(d_i, s_i) = c_i(d_i) + f_{i+1}^*(s_i - d_i) \text{ for } d_i \leq s_i,$$

$$\text{where } f_i^*(s_i) = \min_{d_i \leq s_i} f_i(d_i, s_i), \text{ for } i=1, 2, 3.$$

The boundary condition is  $f_4^*(s_4)=0$  for any  $s_4$ .

- **Optimality table:**

|           |       | State $s_i$ |      |    |      |
|-----------|-------|-------------|------|----|------|
| Stage $i$ | $d_i$ | 0           | 1    | 2  | 3    |
| 3         | 0     | 20          | 20   | 20 | 20   |
|           | 1     | -           | [14] | 14 | 14   |
|           | 2     | -           | -    | 11 | 11   |
|           | 3     | -           | -    | -  | 8    |
|           | min   | 20          | 14   | 11 | 8    |
| 2         | 0     | 45          | 39   | 36 | 33   |
|           | 1     | -           | -    | -  | -    |
|           | 2     | -           | -    | -  | -    |
|           | 3     | -           | -    | -  | -    |
|           | min   |             |      |    |      |
| 1         | 0     | 59          | 53   | 47 | 44   |
|           | 1     | -           | 55   | 49 | [43] |
|           | 2     | -           | -    | 52 | 46   |
|           | 3     | -           | -    | -  | 49   |
|           | min   | 59          | 53   | 47 | 43   |

- **Optimal decision:**

## Ex 2] Cargo-Loading Problem

Consider loading a vessel with stocks of 3 items. Maximum cargo weight is 6 tons. The **weight** and the **value** of each unit of items are listed as follows:

| Item $i$ | Weight (ton) $w_i$ | Value $v_i$ |
|----------|--------------------|-------------|
| 1        | 4                  | \$9         |
| 2        | 2                  | \$5         |
| 3        | 3                  | \$7         |

How should the vessel be loaded to maximize the **total value**?

### (a) IP formulation

- **Variables:**
- **Objective function:**
- **Constraints:**

### (b) Network representation:

Find the **longest path** from the origin to the destination!

**(c) DP formulation**

- **Stage  $i$ :** The  $i$ th item, where  $i=1, 2$ , and  $3$ .
- **State  $s_i$  at stage  $i$ :** Total remaining weight.
- **Decision  $d_i$ :** Number of units of item  $i$  to be loaded.
- **Optimality equation:**

Let  $f_i(d_i, s_i)$  be the *maximum* value obtained when the remaining weight is  $s_i$  and we load  $d_i$  units of item  $i$ :

$$f_i(d_i, s_i) = v_i d_i + f_{i+1}^*(s_i - w_i d_i) \text{ for } w_i d_i \leq s_i,$$

$$\text{where } f_i^*(s_i) = \max_{w_i d_i \leq s_i} f_i(d_i, s_i), \text{ for } i=1, 2, 3.$$

The **terminal condition** is  $f_4^*(s_4) = 0$ .

- **Optimality table:**

| Stage<br><i>i</i> |     | State <i>s<sub>i</sub></i> |   |   |   |    |    |      | <i>w<sub>i</sub></i> | <i>v<sub>i</sub></i> |   |   |
|-------------------|-----|----------------------------|---|---|---|----|----|------|----------------------|----------------------|---|---|
|                   |     | 0                          | 1 | 2 | 3 | 4  | 5  | 6    |                      |                      |   |   |
| 3                 | 0   | [0]                        | 0 | 0 | 0 | 0  | 0  | 0    | 3                    | 7                    |   |   |
|                   | 1   | -                          | - | - | 7 | 7  | 7  | 7    |                      |                      |   |   |
|                   | 2   | -                          | - | - | - | -  | -  | 14   |                      |                      |   |   |
|                   | max | 0                          | 0 | 0 | 7 | 7  | 7  | 14   |                      |                      |   |   |
| 2                 | 0   |                            |   |   |   |    |    |      | 2                    | 5                    |   |   |
|                   | 1   |                            |   |   |   |    |    |      |                      |                      | - | - |
|                   | 2   |                            |   |   |   |    |    |      |                      |                      | - | - |
|                   | 3   | -                          | - | - | - | -  | -  |      |                      |                      |   |   |
|                   | max |                            |   |   |   |    |    |      |                      |                      |   |   |
| 1                 | 0   | 0                          | 0 | 5 | 7 | 10 | 12 | [15] | 4                    | 9                    |   |   |
|                   | 1   | -                          | - | - | - | 9  | 9  | 14   |                      |                      |   |   |
|                   | max | -                          | - | - | - | 10 | 12 | 15   |                      |                      |   |   |

- **Optimal decision:**

### Ex 3] Resource Allocation Problem

ET is about to fly home. For the trip to be successful, the ship's solar relay, wrap drive, and candy maker must all function properly. ET has found 3 mechanics who are willing to help get the ship ready for take-off. The probability that each component will function properly during the trip home is given as a function of the number of mechanics assigned to repair each component:

| $P_{ij}$       | Number of mechanics assigned to component $i$ |      |      |      |
|----------------|---|------|------|------|
|                | 0   | 1    | 2    | 3    |
| 1. Wrap drive  | 0.30  | 0.55 | 0.65 | 0.95 |
| 2. Solar relay | 0.40  | 0.50 | 0.70 | 0.90 |
| 3. Candy maker | 0.45  | 0.55 | 0.80 | 0.98 |

#### (a) IP formulation

- Variables:
  
  
  
- Objective function:
  
  
  
- Constraints:

#### (b) DP formulation

- Stage  $i$ : The  $i$ th task, where  $i=1, 2, 3$ .
- State  $s_i$  at stage  $i$ : Number of mechanics still available.
- Decision  $d_i$ : Number of mechanics assigned to task  $i$

▪ **Optimality equation:**

- Let  $p_i(d_i)$  denote the *probability* of success for task  $i$  if it is assigned  $d_i$  mechanics.
- Let  $f_i(d_i, s_i)$  be the *maximum* probability obtained at stage  $i$  when, among  $s_i$  mechanics still available, we assign  $d_i$  mechanics to task  $i$ . Then, the *recursive equation* is

$$f_i(d_i, s_i) = p_i(d_i)f_{i+1}^*(s_i - d_i) \text{ for } d_i \leq s_i,$$

$$\text{where } f_i^*(s_i) = \max_{d_i \leq s_i} f_i(d_i, s_i), \text{ for } i=1, 2, 3.$$

- The *terminal condition* is  $f_4^*(s_4) = 1$ .

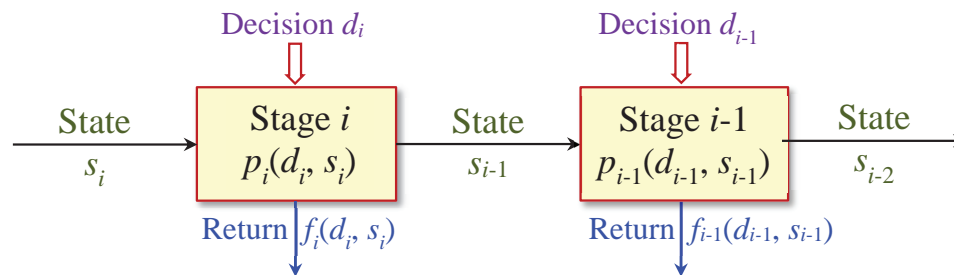

▪ **Optimality table:**

|                |     | 0     | 1      | 2       | 3       |
|----------------|-----|-------|--------|---------|---------|
| 3. Candy maker | 0   | 0.45  | 0.45   | 0.45    | 0.45    |

▪ **Optimal decision:**

### D. Probabilistic DP Models\*

In **deterministic** DP problems, a specification of the current **state** and current **decision** is enough to tell us *with certainty* the new **state** and the **costs** during the current stage. In **probabilistic** (or stochastic) DP problems, the current period's **costs** and/or the next period's **state** may not be known with certainty, even if the current state and decision are known.

#### \* Formulation

- **Stage  $i$** , where  $i=0, 1, \dots, n$ . (*finite* time-horizon!)
- **State  $s_i$** : At the beginning of each stage  $i$ , the system is in some state  $s_i$ .
- **Decision** (or action)  $d_i$ : For every state  $s_i$ , the allowable decision  $d_i$  is available.
- **Transition probabilities** from the current state to the next state:  $p_i(d_i, s_i)$
- **Expected reward** obtained at stage  $i$ :  $f_i(d_i, s_i)$

#### \* Classification

- *Finite* stage model
- *Infinite* stage model  $\Rightarrow$  Markov decision process

\* **Case I: Uncertain Payoffs.** A supermarket chain has purchased 6 gallons of milk from a local dairy. The chain must allocate the 6 gallons to its 3 stores. If a store sells a gallon of milk, then the chain receives revenue of \$2. Any unsold milk is worth just \$.50. Unfortunately, the demand for milk is uncertain, and is given in the following table:

|         | Daily Demand |     |     |
|---------|--------------|-----|-----|
|         | 1            | 2   | 3   |
| Store 1 | 0.6          | 0.0 | 0.4 |
| Store 2 | 0.5          | 0.1 | 0.4 |
| Store 3 | 0.4          | 0.3 | 0.3 |

Use dynamic programming to determine how the supermarket should allocate the 6 gallons of milk among the three stores to maximize the expected revenue.

- Expected revenue  $r_i(d_i)$  for each allocation of milk to a store:

| $r_i(d_i)$ | Allocation |        |        |        |
|------------|------------|--------|--------|--------|
|            | 0          | 1      | 2      | 3      |
| Store 1    | \$0.00     | \$2.00 | \$3.10 | \$4.20 |
| Store 2    | \$0.00     |        |        | \$4.35 |
| Store 3    | \$0.00     | \$2.00 | \$3.40 | \$4.35 |

#### DP formulation

- **Stage  $i$ :** The  $i$ th store, where  $i=1, 2, 3$ .
- **State  $s_i$ :** Amount of milk available for allocation.
- **Decision  $d_i$ :** Amount of milk allocated for store  $i$ .
- **Payoff  $r_i(d_i)$ :** Expected revenue earned at store  $i$  with  $d_i$ .

### ▪ Optimality equation

Let  $f_i(d_i, s_i)$  be the expected revenue earned when  $s_i$  gallons of milk is available and  $d_i$  gallons of them are allocated for store  $i$ . Then, the recursive equation is

$$f_i(d_i, s_i) = r_i(d_i) + f_{i+1}^*(s_i - d_i) \text{ for } d_i \leq s_i,$$

$$\text{where } f_i^*(s_i) = \max_{d_i \leq s_i} f_i(d_i, s_i), \text{ for } i=1, 2, 3.$$

The boundary condition is  $f_4^*(s_4) = 0.5s_4$  for all  $s_4$ .

### ▪ Optimality table

|   | $d_i$ | State $s_i$ |      |        |      |      |      |        | $r_i(d_i)$ |
|---|-------|-------------|------|--------|------|------|------|--------|------------|
|   |       | 0           | 1    | 2      | 3    | 4    | 5    | 6      |            |
| 3 | 0     | 0           | 0.50 | 1.00   | 1.50 | 2.00 | 2.50 | 3.00   | 0.00       |

|   | 1     |             | 2.00 | 4.00   | 6.00 | 7.40 | 8.65 | [9.75] | 2.00       |
|   | 2     |             | -    | 3.10   | 5.10 | 7.10 | 8.50 | 9.75   | 3.10       |
|   | 3     |             | -    | -      | 4.20 | 6.20 | 8.20 | 9.60   | 4.20       |
|   | max   | 0           | 2.00 | 4.00   | 6.00 | 7.40 | 8.65 | 9.75   |            |

### ▪ Multiple optimal solutions

Assign (1, 3, 2) or (2, 2, 2) with  $z =$

\* **Case II: Uncertain States:** A gambler has \$2. He is allowed to play a game of chance 4 times, and his goal is to maximize his probability of finishing with at least \$6. If the gambler bets  $d$  dollars on a play of the game, then with probability 0.40, he wins the game and increases his capital position by  $d$  dollars; There is a probability of 0.6 of losing the game, in which case he loses  $d$  dollars. On any play of the game, the gambler may not bet more money than he has. We assume that bets of zero dollars (i.e., not betting) are permissible.

Using dynamic programming, determine the betting strategy that will maximize his chances of finishing with at least \$6 by the end of the fourth game.

#### ▪ DP formulation

- Stage  $i$ : He has  $i$  more games to play.
- State  $s_i$ : Number of \$1 chips in hand at stage  $i$ .
- Decision  $d_i$ : Number of \$1 chips to bet at stage  $i$ .
- Payoff  $r_i(d_i)$  \$ $d$  if he wins or -\$ $d$  if he loses a game.

#### ▪ Optimality equation

- Let  $f_i(d_i, s_i)$  be the probability that he will finish with at least \$6, given that he bets  $d_i$  among  $s_i$  dollars available at stage  $i$ . Then, the recursive equation is

$$f_i(d_i, s_i) = 0.6f_{i-1}^*(s_i - d_i) + 0.4f_{i-1}^*(s_i + d_i) \text{ for } d_i \leq s_i$$

where  $f_i^*(s_i) = \max_{d_i \leq s_i} f_i(d_i, s_i)$ , for  $i=1, 2, 3, 4$ .

- The boundary condition is

$$f_0(s_0) = \begin{cases} 1 & \text{if } s_0 \geq \$6 \\ 0 & \text{if } s_0 < \$6 \end{cases}$$

### ▪ Optimality table

| Stage | Decision | State |       |        |        |        |        |        |
|-------|----------|-------|-------|--------|--------|--------|--------|--------|
|       |          | 0     | 1     | 2      | 3      | 4      | 5      | 6      |
| 0     | max      | 0     | 0     | 0      | 0      | 0      | 0      | 1      |
| 1     | 0        | 0     | 0     | 0      | 0      | 0      | 0      | 1      |
|       | 1        |       | 0     | 0      | 0      | 0      | 0.4    | 0.4    |
|       | 2        |       |       | 0      | 0      | 0.4    | 0.4    | 0.4    |
|       | 3        |       |       |        | 0.4    | 0.4    | 0.4    | 0.4    |

### ▪ Optimal betting strategy

If he plays the game with \$2,  $P[s_0 \geq \$6 \mid 4 \text{ plays}] = 0.1984$ .

# From the Markov decision process,

it can be shown that  $P[s_0 \geq \$6 \mid \infty \text{ plays}] = 0.2105$ .

### E. Optimal Stopping Problems\*

The theory of **optimal stopping** is concerned with the problem of choosing a time to take a particular action, based on *sequentially* observed random variables, in order to maximize an **expected reward** or minimize an **expected cost**. Problems of this type are found in the area of statistics, economics, and mathematical finance.

Optimal stopping problems can often be written in the form of an **optimality equation**, and are therefore often solved using **dynamic programming**:

- **Stage  $i$ :** A sequence of random variables.
- **State  $s_i$ :** Observed value of the random variable.
- **Decision  $d_i$ :** Stop ( $d_i=1$ ) or go ( $d_i=0$ ).
- **Reward  $r_i(d_i, s_i)$**

However, they often have a **special structure** that simplifies the determination of optimal policies.

#### Ex 1] Asset Selling Problem

The market value of a **used car** is estimated at \$3,000. The owner can get more than this amount, but is willing to entertain offers from the first **three** prospective buyers who respond to the advertisement (which means that a decision must be made no later than the time the third offer is received). The offers are expected to be \$3,000, \$3,300, \$3,700, and \$4,200, with **equal** probabilities. Naturally, once an offer is accepted, all later offers are discarded. The objective is to set an acceptance limit that can be used to evaluate each offer.

Develop an **optimal stopping rule** for the owner.

### ▪ DP formulation

- **Stage  $i$ :** The  $i$ th buyer, where  $i=1, 2, 3$ .
- **State  $s_i$ :** Buyer's offer at stage  $i$ .
- **Decision  $d_i$ :** Accept the offer ( $d_i=1$ ) or reject it ( $d_i=0$ ).

### ▪ Optimality equation

Let  $f_i(d_i, s_i)$  be the **expected profit** on day  $i$  given that the offer is  $s_i$  and the decision is  $d_i$ . Then, the **recursive equation** is

$$f_i(d_i, s_i) = \begin{cases} s_i & \text{if } d_i = 1 \\ \sum_{\forall s_{i+1}} p(s_{i+1}) f_{i+1}^*(s_{i+1}) & \text{if } d_i = 0 \end{cases}$$

where  $f_i^*(s_i) = \max_{d_i \in \{0,1\}} f_i(d_i, s_i)$  for  $i=1, 2, \dots, 3$ .

The **terminal condition** is  $f_4(s_4) = 0$ .

### ▪ Optimality table

| Stage | Decision | State |      |      |      |
|-------|----------|-------|------|------|------|
|       |          | 3000  | 3300 | 3700 | 4200 |
| 3     | Stop     | 3000  | 3300 | 3700 | 4200 |
|       | Go       | 0     | 0    | 0    | 0    |
|       | max      | 3000  | 3300 | 3700 | 4200 |
| 2     | Stop     | 3000  |      | 3700 | 4200 |
|       | Go       | 3550  |      | 3550 | 3550 |
|       | max      | 3550  |      | 3700 | 4200 |
| 1     | Stop     | 3000  | 3300 |      | 4200 |
|       | Go       | 3750  | 3750 |      | 3750 |
|       | max      | 3750  | 3750 |      | 4200 |

▪ **Expected revenue:**  $f_0 =$

## Ex 2] Random Walk Model

An urn initially has 6 **red** and 4 **blue** balls. At each stage, you may *randomly* choose a ball from the urn; if the ball is **blue**, then \$1 is earned, and if it is **red**, then \$1 is lost. The chosen ball is discarded. At any time, you can decide to **stop** playing or choose another ball. To maximize the player's total *expected net return*, let's analyze this as a *probabilistic* DP problem.

### ▪ DP formulation

- **State**  $(i, j)$ : Currently  $i$  red and  $j$  blue balls in the urn.
- **Decision** when the state is  $(i, j)$ : (*Stop*, *Continue*)
- **Transition probabilities** from  $(i, j)$ :  
 $P[\text{Pick a red ball}] = P[\text{from } (i, j) \text{ to } (i-1, j)] = i/(i+j)$   
 $P[\text{Pick a blue ball}] = P[\text{from } (i, j) \text{ to } (i, j-1)] = j/(i+j)$
- **Maximum** expected additional return at state  $(i, j)$ :  $v(i, j)$

### ▪ Optimality equation:

$$v(i, j) = \max \left\{ 0, \frac{i}{i+j} [v(i-1, j) - 1] + \frac{j}{i+j} [v(i, j-1) + 1] \right\}$$

with the *boundary* conditions,  $v(i, 0) = 0$  and  $v(0, j) = j$ .

### ▪ Optimality table:

|        |   |                          |        |        |        |        |        |        |
|--------|---|--------------------------|--------|--------|--------|--------|--------|--------|
| Number | 4 | 4                        | 3.2000 | 2.4000 | 1.6571 | 1.0000 | 0.4444 | 0.0667 |
| of     | 3 | 3                        | 2.2500 | 1.5000 | 0.8500 | 0.3429 | 0.0000 | 0.0000 |

| balls  | 1 | 1                        |        | 0.0000 | 0.0000 | 0.0000 | 0.0000 | 0.0000 |
| $j$    | 0 | 0                        | 0      | 0      | 0      | 0      | 0      | 0      |
|        |   | 0                        | 1      | 2      | 3      | 4      | 5      | 6      |
|        |   | Number of red balls, $i$ |        |        |        |        |        |        |

- Optimal strategy?
- Total expected net return,  $v(6, 4) =$

### Ex 3] Secretary Problem

An employer would like to choose the **best candidate** among 4 competing applicants that arrive in a random order. After each interview, the position of the interviewee in the total order is revealed vis-à-vis already interviewed applicants. The interviewer has to decide, irrevocably, whether to **accept** the candidate for the position or to **reject** the candidate. The **objective** is to accept the **best** candidate with high **probability**.

#### ▪ DP formulation

- **Stage**  $i$  = The  $i$ th applicant, where  $i=1, 2, \dots, n$ .
- **State** at the  $i$ th stage =  $\begin{cases} 1 & \text{if the } i\text{th applicant is a candidate} \\ 0 & \text{Otherwise} \end{cases}$
- **Decision** at stage  $i$  = {Stop, Go}
- **Reward**: Probability of selecting the **absolutely** best choice.
  - $\phi_i$  if we *stop* at stage  $i$  with a “**candidate**”.
  - $\pi_i$  if we *go* at stage  $i$ .

|          |      | State     |                 |
|----------|------|-----------|-----------------|
|          |      | Candidate | Not a candidate |
| Decision | Stop | $\phi_i$  | 0               |
|          | Go   | $\pi_i$   | $\pi_i$         |

#### ▪ Optimality equation

- Recursive equation:

If **stop** at stage  $i$   $\phi_i = i/n$ .

If **go** at stage  $i$   $\pi_i = \frac{1}{i+1} \max(\phi_{i+1}, \pi_{i+1}) + \frac{i}{i+1} \pi_{i+1}$ .

The **boundary** condition is  $\pi_n = 0$ .

- Consider the case in which  $n = 4$ .

- Optimality table

| Stage | Decision | State     |               | Transition to candidate |
|-------|----------|-----------|---------------|-------------------------|
|       |          | Candidate | Not candidate |                         |
| 4     | stop     | [1]       | 0             | 1/4                     |
|       | go       | 0         | 0             |                         |
|       | max      | 1         | 0             |                         |
| 3     | stop     | [3/4]     | 0             | 1/3                     |
|       | go       | 1/4       | [1/4]         |                         |
|       | max      | 3/4       | 1/4           |                         |
| 2     | stop     | [2/4]     | 0             | 1/2                     |
|       | go       |           |               |                         |
|       | max      | 2/4       | 5/12          |                         |
| 1     | stop     | 1/4       | 0             | 1/1                     |
|       | go       | [11/24]   | 11/24         |                         |
|       | max      | 11/24     | 11/24         |                         |

- Stopping region:  $\{2, 3, 4\}$
- Success rate:  $P[\text{Win} \mid n=4] = \pi_0 =$

# Lindley (1961) said, “If, in real life, this process works between 18 and 40 ( i.e., for 22 years ), one should never propose until age 26.”

He explained, “Either many people do not pursue an optimal strategy or else they have a different utility function.”
